I. INTRODUCTION

A. Purpose of Report

This Technical Memorandum summarizes and evaluates the results of the Phase 2 Remedial Investigation (RI) conducted at the Eagle Zinc Company site (the "Site"), located in Hillsboro, Illinois. ENVIRON International Corporation (ENVIRON) has prepared this Technical Memorandum on behalf of the Eagle Zinc Parties (the "Parties") as part of the Remedial Investigation/Feasibility Study (RI/FS) for the Site. The RI/FS is being completed pursuant to the Statement of Work (SOW) presented in the December 31, 2001 Administrative Order on Consent (AOC) between the Parties and the U.S. Environmental Protection Agency (USEPA). All Phase 2 investigations were conducted in accordance with the following USEPA-approved documents: the AOC; the SOW; the July 2002 *Remedial Investigation/Feasibility Study Work Plan* (the "RI/FS Work Plan"); the March 2003 *Technical Memorandum, Remedial Investigation, Phase 1: Source Characterization* (the "Phase 1 Technical Memorandum"); and a May 30, 2003 letter proposal for supplementary sampling, which was conditionally approved by USEPA in a letter dated June 9, 2003.

As stated in the SOW and RI/FS Work Plan, the overall purpose of the RI is to investigate the Site's physical characteristics, identify sources of contamination, and determine the nature and extent of contamination at the Site. Consistent with the AOC governing the RI/FS, the RI has been designed to complement the prior investigations conducted at, and in the vicinity of the Site. The primary focus of the RI is to characterize the nature and extent of contamination at the site, to assess potential migration pathways by which the contaminants could impact human or ecological receptors, and to evaluate potential risks to those receptors. The RI includes two phases of investigation: Phase 1 (Source Characterization), and Phase 2 (Migration Pathway Assessment). The Phase 1 Technical Memorandum was submitted to USEPA and IEPA in March 2003. The results of both phases of the RI will be interpreted as a basis for performing a baseline risk assessment to establish the need for future remedial response activities for the Site.

The purpose of this Technical Memorandum is to summarize results obtained from the Phase 2 investigation, which involved the assessment of potential migration pathways, including ground water and surface water.

B. Report Organization

Section I describes the purpose and organization of this report. Section II of this report provides a summary of the work conducted as part of the Phase 2 RI. Section III describes the physical characteristics of the areas investigated during both Phases of the RI. Section IV presents the results of the Phase 2 RI. Section V presents an updated Site Conceptual Model. A detailed discussion of Site background information, including a description of the Site, the history of the Site, and a summary of previous investigations, was included in the RI/FS Work Plan and the March 2002 *Preliminary Site Evaluation Report* ("the PSE Report").

II. PHASE 2 – MIGRATION PATHWAY ASSESSMENT

The Phase 2 field activities were conducted at the Site between March 10, 2003 and March 19, 2003. In addition, supplementary sampling activities were conducted between June 19, 2003 and June 23, 2003. All field activities were conducted and/or supervised by ENVIRON. All piezometer installation, monitoring well installation, temporary well installation, well development, and residue pile test excavation activities were conducted by Philip Services, Inc. (Philip). All laboratory analyses were conducted by EnChem, Inc. (EnChem) of Green Bay, Wisconsin. Site surveying work was conducted by Hurst-Rosche Engineers, Inc. (Hurst-Rosche) of Hillsboro, Illinois. Tables II-1 through II-4 provides a summary of all investigative samples collected as part of Phase 2 of the RI.

A. Site Surveying

As discussed below, Hurst-Rosche surveyed the locations and elevations of the piezometers, monitoring wells, temporary monitoring wells, and a staff gage installed in the southwest pond. Based on field conditions (e.g., marshy conditions, steep terrain, etc.), some piezometer and monitoring well locations were adjusted from the proposed locations the minimum distance necessary to allow drill rig access (see Section B.1 below).

B. Ground Water Investigation

In accordance with the RI/FS Work Plan and certain augmentations to the Phase 2 program approved by the USEPA, the scope of the ground water investigation included:

- Installation of six (6) permanent piezometers and four (4) temporary piezometers at the approximate locations depicted on Figure VI-2 of the Phase 1 Technical Memorandum, with ground water elevations determined as discussed in the RI/FS Work Plan. All piezometers were installed between March 10, 2003 and March 12, 2003

- Installation of eleven (11) additional permanent monitoring wells at the approximate locations depicted on Figure VI-2 of the Phase 1 Technical Memorandum. Monitoring wells MW1 through MW10 were installed between March 12, 2003 and March 15, 2003. Monitoring well MW11 was installed on June 19, 2003.

- Installation of three (3) temporary monitoring wells on off-Site properties, not owned by Eagle Zinc, located west of the southwest portion of the Site. These temporary wells were installed on June 19 and 20, 2003.

- Sampling of the newly installed and existing monitoring wells and off-Site temporary monitoring wells as discussed in the RI/FS Work Plan. With the exception of MW11, which was installed in June 2003, all on-Site permanent monitoring wells were sampled on March 18, 2003 and March 19, 2003. The three off-Site temporary monitoring wells and MW11 were sampled on June 20, 2003.

- Installation and surveying of a staff gauge in the southwest pond to determine the elevation of the pond surface water relative to ground water. The staff gauge was installed on March 10, 2003.

1. Piezometer Installation

Six (6) permanent and four (4) temporary piezometers were installed at the Site to provide a preliminary confirmation of the pattern of groundwater flow and to confirm locations for additional permanent monitoring wells. The piezometers were installed as close as possible to their proposed locations; however, physical limitations, such as steep terrain, marshy conditions and excessive vegetation, warranted deviations from five of the proposed locations:

- Permanent piezometer P-1 was installed approximately 90 feet south of its proposed location.

- Permanent piezometer P-2 was installed approximately 170 feet west of its proposed location.
- Permanent piezometer P-3 was installed approximately 90 feet south of its proposed location.
- Temporary piezometer P-9 was installed approximately 90 feet south of its proposed location.
- Temporary piezometer P-10 was installed approximately 280 feet southwest of its proposed location.

The surveyed locations of the piezometers are shown on Figure II-1.

The piezometers were designated P1 through P10, with the permanent piezometers numbered P1 through P6 and the temporary piezometers numbered P7 through P10. All of the piezometers were installed using a truck-mounted direct-push drilling apparatus (i.e., Geoprobe). Two-inch outside diameter macro-core soil samples were collected continuously to an appropriate depth below the top of the saturated zone and soil boring logs were prepared by an ENVIRON geologist. All soil cores were screened for organic vapors at 6-inch intervals using a photoionization detector (PID). To construct each piezometer, a one-inch diameter section of PVC screen and riser pipe was placed in the core hole and a clean sand filter pack was placed around the PVC, generally to a depth of one to two feet above the top of the screen. The screen was placed so as to straddle the water table. A seal of granular bentonite was then placed in the annular space above the sand pack. The permanent piezometers were completed with stick-up type protective casings with locking caps. The temporary piezometers were completed with non-locking PVC caps. Piezometer drilling and construction logs are provided in Appendix A.

Water level measurements were collected from all piezometers, as well as pre-existing monitoring wells G101 through G109 and converted to water level elevations using surveyed benchmarks at the top of the piezometer casings. Preliminary ground water elevations determined from the piezometers and pre-existing monitoring wells confirmed that the locations selected for the additional

monitoring wells were appropriate for monitoring ground water quality downgradient of potential areas of concern for soils identified during the Phase 1 investigation.

Following the complete round of synoptic water level measurement conducted in March 2003 immediately prior to ground water sampling, the four temporary piezometers (P7 through P10) were abandoned by removing the PVC, returning the soil cores to the borehole, and sealing the remainder of the borehole with granular bentonite.

2. Monitoring Well Installation

Eleven (11) monitoring wells (MW1 through MW11) were installed at the Site using the hollow-stem auger drilling method. The surveyed locations of the monitoring wells are shown on Figure II-1. The following adjustments were made to the array of Site monitoring wells in the field:

- At the onset of the Phase 2 fieldwork, pre-existing monitoring well G108 was found to have been damaged and partially filled with rocks. This well was properly abandoned by Philip Services by removing the entire well, including the screen and riser, and sealing the remaining hole with bentonite.

- The location of the proposed monitoring well depicted on Figure VI-2 of the Phase 1 Technical Memorandum in the southwest corner of the Site was inaccessible, as the location depicted on this figure was within the steep ravine located between the southwest pond embankment and higher ground to the south of the Site. Therefore, this monitoring well (MW8) was installed on the pond embankment itself, as close as feasible to the proposed location (approximately 60 feet north of the proposed location). The selected location for MW8 is directly downgradient of the southwest pond and upper portions of the Western Drainageway. As MW8 was installed close to G108 and serves equally as a downgradient monitoring point, well G108 was not replaced with a new monitoring well.

- The location initially proposed for a new monitoring well near the on-Site drainageway leading into the pond at the southwest corner of the Site was inaccessible in both March 2003 and June 2003, as a broad area of standing water covered the proposed location. Therefore, this monitoring well (MW11) was installed in June 2003 at the closest accessible location, which was approximately 200 feet east of the proposed location.

Split-spoon samples were collected at five-foot intervals from the ground surface to the completion depth of the monitoring well and the samples were logged by the ENVIRON geologist.[1] Following the completion of a 6-inch diameter borehole, 2-inch inside diameter sections of schedule-40 PVC screen and riser pipe were placed in the borehole and a clean sand filter pack was placed around the screened interval. The well screen was installed such that it straddled the water table. A bentonite seal was then placed in the well annulus and the monitoring well was completed with a stick-up type protective casing with a locking cap. Drilling and well construction logs for the monitoring wells are presented in Appendix A.

Each newly installed monitoring well was developed no sooner than 12 hours following well installation. In addition, to ensure adequate flow of ground water into the wells, pre-existing wells G101 through G109 were redeveloped. Well development consisted of the removal of a minimum of three times the measured casing volume of water plus three times the saturated volume of the monitoring well sand pack using dedicated polyethylene bailers. Well development was deemed complete when this volumetric criterion and a reasonably clear discharge was achieved.[2]

3. Temporary Monitoring Well Installation

As proposed in ENVIRON's May 30, 2003 letter to the USEPA and approved by the USEPA in a letter dated June 9, 2003, three (3) temporary monitoring wells were installed on off-Site properties on June 19 and 20, 2003 to provide

[1] Prior to installation with the hollow-stem auger drilling rig, soils at monitoring wells MW01 and MW02 were first logged using a Geoprobe drilling apparatus (i.e., by collecting 4-foot long macro-core samplers).
[2] While noted in the RI/FS Work Plan, field parameters were not measured during well development.

supplementary ground water data in the area west of the southwest portion of the Site.

The temporary wells were designated TW5 through TW7 and were installed using a truck-mounted direct-push drilling apparatus (i.e., Geoprobe). Two-inch outside diameter macro-core soil samples were collected continuously to an appropriate depth below the top of the saturated zone and soil boring logs were prepared by an ENVIRON geologist. All soil cores were screened for organic vapors at 6-inch intervals using a photoionization detector (PID). To construct each temporary well, a one-inch diameter section of PVC screen and riser pipe was placed in the core hole and a clean sand filter pack was placed around the PVC, generally to a depth of one to two feet above the top of the screen. The screen was placed so as to straddle the water table. A seal of granular bentonite was then placed in the annular space above the sand pack. The temporary wells were completed with non-locking PVC caps. Drilling and construction logs for the temporary wells are provided in Appendix A. The temporary wells were developed using the procedures described above for the permanent monitoring wells. Field parameters were not measured during development of the temporary wells.

Following surveying and a complete round of synoptic water level measurement conducted on June 23, 2003, the temporary wells were abandoned by removing the PVC, returning the soil cores to the borehole, and sealing the remainder of the borehole with granular bentonite.

4. Water Level Measurement

On March 17, 2003, prior to initiation of ground water sampling, an electronic water level meter was used to measure the depth to ground water in each monitoring well and piezometer. The measurements were made to the nearest one hundredth (0.01) of a foot relative to a surveyed and marked location at the top of the well casing. In addition, the elevation of the southwest pond was determined using a surveyed staff gage. The calculated piezometer, monitoring well, staff gage, and water level elevations are summarized in Table II-5. The piezometric data were used to construct a Site-wide ground water contour map. A second

complete set of water level measurements was made on June 23, 2003, which included MW11 and the off-Site temporary wells. These data are also presented in Table II-5. Shallow ground water contour maps for the two measurement dates are presented as Figures IV-1 and IV-2, respectively.

5. Ground Water Sampling

Following the completion and development of the newly installed permanent and temporary monitoring wells, all pre-existing and newly installed wells were sampled for TAL metals and sulfate (with the exception of sulfate from MW11).[3] In addition, four of the ground water samples (MW1, MW4, MW8, and G107) were analyzed for TCL organic compounds and PCBs. The metals analyses were conducted using both field-filtered and unfiltered samples to determine dissolved and total metals concentrations, respectively.

For the ground water sampling program conducted in March 2003, field duplicate samples were collected at locations where the full list of analyses (i.e., TAL Metals, sulfate, and TCL Organics) were performed and submitted to the laboratory for analysis of the same parameters at a rate of 1 out of 20.[4] A minimum of 1 out of 20 samples were designated as a Matrix Spike/Matrix Spike Duplicate (MS/MSD) sample. Based on the number of ground water samples (19), during the ground water sampling program conducted in March 2003, one field duplicate sample was collected at MW1 and one MS/MSD was collected at MW1.

All three temporary wells and on-Site monitoring well MW11 were sampled on June 20, 2003. The sample collected from MW11 was designated as the MS/MSD and a field duplicate sample was collected from MW11.

A peristaltic pump was used to purge and sample all permanent and temporary monitoring wells. During well purging, measurements for field parameters (pH, specific conductance, temperature, and dissolved oxygen) were made. While

[3] As proposed in ENVIRON's May 30, 2003 letter to USEPA, MW11 was sampled for TAL Metals only. In addition, monitoring wells MW-A, MW-B, MW-D and MW-E, which were installed and sampled pursuant to a UST compliance program under the oversight of IEPA, were not sampled. As proposed in ENVIRON's May 30, 2003 letter to USEPA, the three off-Site temporary wells were sampled for TAL Metals (dissolved and total). Additionally, monitoring well G-108 was found to be damaged and was subsequently abandoned.

[4] The field duplicate sample for the VOC fraction of TCL Organics was inadvertently not analyzed by the laboratory. However, as discussed in Section IV.A.2.c, no VOCs were detected in any of the ground water samples.

purging, field parameters were monitored continuously using a flow-through sampling cell. Monitoring well purging was considered complete when a minimum of three times the measured casing volume had been removed, and the field-measured parameters of pH, specific conductance, and temperature had stabilized. Monitoring wells G-101, G-105, G-107, MW8, MW9 and MW10 and temporary wells TW5 and TW7 pumped dry before the volumetric criterion was reached. Following one or more pumping episodes in which these wells went dry, these wells were sampled once a sufficient amount of water had recharged in the well. Only wells G-107, TW5 and TW7 did not meet the volumetric purge criteria. Monitoring well sampling details are included in Appendix B.

Filtered and unfiltered ground water samples were collected for the TAL Metals analyses. Field filtering was conducted using dedicated 0.45-micron filters.

C. Surface Water Investigation

As described in the RI/FS Work Plan, each surface water sample was co-located with a Phase 1 sediment sample that was either: (1) located on, or downstream of the Site and exhibited elevated metals concentrations; or (2) represented an upstream location not expected to have been impacted by Site operations. Surface water samples were collected in both of the Site's two major surface water drainageways (i.e., upstream and downstream of storm water Outfalls 1 and 2[5]). As proposed in the Phase 1 Technical Memorandum, in March 2003, surface water samples were collected at a total of ten (10) locations: three (3) within the eastern drainageway; and seven (7) within the western drainageway (includes two samples from the southwest pond). Surface water samples were collected in both drainageways on March 10, 2003 and March 19, 2003. As proposed in ENVIRON's May 30, 2003 letter to USEPA and approved by USEPA in a letter dated June 9, 2003, three additional surface water samples were collected in the Western Drainageway on June 13, 2003.

On both sampling dates, sufficient surface water was present at each proposed location to allow for the collection of a surface water sample. The surface water samples were collected as grab samples by submerging the sample container with the open end

[5] Outfall designations associated with the site's National Pollutant Discharge Elimination System (NPDES) storm water discharge permit (Permit No. IL0074519), which was terminated by IEPA on July 10, 2003 in response to the cessation of operations at the site.

facing upstream. For samples containing a preservative or fixing agent, the samples were collected using a laboratory-cleaned glass sample jar and immediately transferred to the proper sample container. Sample collection was performed in such a way that disturbance of bottom sediments was minimized during sample collection. In both drainageways, the sampling activities proceeded from downstream to upstream so that any disturbed sediment did not impact subsequent sampling.

All surface water samples collected in March 2003 were analyzed for TAL Metals and sulfate. In addition, as shown on Figure II-2, six (6) of the samples (SW-WD-7, SW-WD-9, SW-WD-10, SW-WD-PN, SW-ED-11, and SW-ED-13) were analyzed for TCL organic compounds and PCBs. Field duplicate samples were collected at locations where the full list of analyses were performed and submitted for laboratory analysis of the same parameters at a rate of 1 out of 20. A minimum of 1 out of 20 samples were designated as a Matrix Spike/Matrix Spike Duplicate (MS/MSD) sample. Based on the number of surface water samples (10), one field duplicate sample was collected at SW-WD-7 and one MS/MSD was collected at SW-WD-9.[6]

The three additional surface water samples collected on June 13, 2003 (SW-WD-6-061303, SW-WD-11, and SW-WD-12) were analyzed for TAL Metals. The sample collected on this date at SW-WD-6 was designated the MS/MSD and a field duplicate was collected at this location. The additional surface water samples were approved by USEPA a letter dated June 9, 2003.

D. Supplementary Residue Sampling

During Phase 1 of the RI, three of the 15 residue pipes/groups of piles (RR1-3, RR2-11 and MP1-21) had a Toxicity Characteristic Leaching Procedure (TCLP) lead concentration that exceeded the RCRA hazardous waste threshold of 5.0 mg/L. As proposed in the Phase 1 Technical Memorandum, these three residue piles/pile groups were further characterized by subdividing each pile/group into imaginary sections and collecting one gross composite sample from each section for laboratory analysis of TCLP lead. The purpose of the supplementary sampling was to better define sections of the piles that exceed the TCLP RCRA hazardous waste threshold value for lead of 5.0 mg/L.

[6] The MSD sample for PCBs analysis was not analyzed as the bottle broke during shipment to the laboratory. However, as noted in Section IV.B.1.d, no PCBs were detected in any of the surface water samples.

The locations of the residue piles sampled and the pile sections represented by the composite samples are shown on Figure II-3.

Based on volumetric estimates and pile layout, each pile was divided into a number of equal sections. Eight (8) samples were collected from pile RR2-11, two (2) samples were collected from pile RR1-3, and three (3) samples were collected from the MP1-21 piles. Each sample was collected as a composite of three sample increments, and was collected either as depth composites or area composites.[7] The sample compositing methodology was as discussed in the RI/FS Work Plan.

Each composite sample was analyzed for lead using the TCLP. A field duplicate was collected for sample R-RR1-3-S1D (rate of 1 out of every 20 samples). Sample R-MP1-21-S3 was designated the MS/MSD.

E. Soil pH Sampling

To determine the general range of Site-wide soil pH conditions, one soil sample was collected for laboratory soil pH analysis from each of the 20 soil borings completed for installation of the monitoring wells and piezometers. The majority of the soil pH samples were collected one foot below the depth at which undisturbed native soil was encountered.[8]

[7] Similar to the sampling procedure employed during the Phase 1 residue sampling program, the depth composites were collected at three equally spaced depths within the pile by completing test trenches. Area composites, consisting of sample increments spaced evenly across the section to be sampled, were collected for lower, horizontally extensive piles.

[8] At several locations, a slightly deeper interval was selected for collection of the pH sample, as the pH samples were collected from split-spoon samples that, in accordance with the RI/FS Work Plan, were taken from the monitoring well boreholes at 5-foot intervals. However, all pH samples are believed to be representative of the uppermost native soils encountered in the borings, which ranged in texture from silty clay to silty sand.

III. PHYSICAL CHARACTERISTICS OF THE STUDY AREA

The physical characteristics of the areas of the Site were discussed in detail in the March 2002 Preliminary Site Evaluation (PSE) Report, as well as the July 2002 RI/FS Work Plan. This information was assembled through inquiries made during completion of the PSE and from previous environmental reports concerning the Site. Information relevant to both phases of the RI is discussed below. No significant differences in the physical characteristics of the Site were observed during the Phase 2 investigations, as compared with previous investigation phases and Site inspections.

A. Surface Features

The Site's surface topography, storm water drainage, water bodies, and physiographic setting are described in detail in Section II.A.3.b of the RI/FS Work Plan. The historic plant residues are discussed in Section II.A.4 of the RI/FS Work Plan. A topographic survey map of the Site was included in Appendix A of the Phase 1 Technical Memorandum. All plant operations, including residue processing operations, ceased in late 2002 and early 2003. The thickness of surface residues encountered at each well/piezometer location is depicted on each soil boring log presented in Appendix A.

B. Local Meteorology

Meteorological data for the Site area are provided in Section II.A.3.a of the RI/FS Work Plan. In addition to the meteorological information presented in the RI/FS Work Plan, the Phase 1 Technical Memorandum included a wind rose diagram for the Springfield, Illinois airport, which is located approximately 30 miles north of the site, but is expected to display similar average wind directions. The wind rose diagram, which displays the dominant average wind directions and ranges of wind speed for the year 1987, indicates that the dominant wind direction is towards the north and north-northeast, with moderate frequency in other eastward directions, and the lowest frequencies in the westward directions. The prevailing northward wind direction is consistent with the generalized meteorological information provided in the RI/FS Work Plan.

C. Surface Water Hydrology

The surface water hydrology of the Site and surrounding area is described in detail in Section II.A.3.b of the RI/FS Work Plan. Additional information concerning surface water quality in the Site's drainage systems and the interaction between the southwestern pond and ground water was collected as part of the surface water and ground water investigations conducted during Phase 2 and is discussed further below. Surface water flow in the drainageways was greater during the Phase 2 investigations than previously observed, as the Site area had experienced significant rainfall during the winter and spring of 2003. The volumetric flow in the drainageways appears to vary significantly on a seasonal and perennial basis.

D. Site Geology

Information concerning the soils, overburden units (glacial deposits) and bedrock units that underlie the Site was presented in Section II.A.3.d of the RI/FS Work Plan. Field observations made during completion of the Phase 1 and Phase 2 soil borings indicate that the overburden unit within the depth intervals investigated generally consists of a sequence of interlayered brown to gray clay, silty clay, and sandy clay, and silty or clayey sand.

E. Site Hydrogeology

Information concerning the Site hydrogeology was presented in Section II.A.3.e of the RI/FS Work Plan. Ground water was measured in the monitoring wells at depths ranging from approximately 2 to 17 feet below ground surface (bgs).

F. Demography and Land Use

According to the 2000 census, approximately 2,800 people lived within a 1-mile radius of the Site and approximately9,300 people lived within a 5-mile radius of the Site. Land use characteristics of the Site and surrounding area are described in Section II.A.2 of the RI/FS Work Plan.

G. Ecology

As discussed in the Phase 1 Technical Memorandum, an Ecological Risk Screening Evaluation is a component of the Baseline Risk Assessment task. As part of this evaluation, a preliminary site visit was conducted by Limno-Tech, Inc. (LTI) during implementation of the Phase 1 field activities. The objectives of the site visit were to: 1) identify on-site or relevant off-site habitats, ecological receptors, contaminant source(s) and contaminant(s) migration routes; and 2) assess to the extent possible whether a potential for present or future ecological impacts exists based on contaminants, receptor, and potential migration pathways. No additional activities associated with the Ecological Risk Screening Evaluation were conducted during Phase 2 of the RI and no conclusions concerning the ecology of the Site or adjacent areas have been made by LTI.

IV. NATURE AND EXTENT OF CONTAMINATION

A. Ground Water Investigation

1. Ground Water Flow

Using ground water levels measured in the monitoring wells and piezometers on March 17, 2003, a ground water contour map (Figure IV-1) was constructed, which shows the inferred pattern of shallow ground water flow across the Site. The shallow ground water flow pattern is consistent with the previous interpretation presented on Figure II-3 of the RI/FS Work Plan, in that it shows an inferred southward/southwestward ground water flow direction in the western and southwestern portions of the Site and an eastward/southeastward flow direction in eastern portions of the Site. These flow regimes are separated by a roughly north-south trending ground water divide. Based on the existence of the divide, ground water in the northwestern most portion of the Site may locally exhibit a northward or northwestward flow component. However, based on the local topography, most if not all of the Site's ground water is believed to ultimately flow either southwestward (towards and parallel with the Western Drainageway) or eastward/southeastward (towards and parallel with the Eastern Drainageway). In all areas of the Site, the shallow ground water flow pattern generally reflects the surface topography.

A second ground water contour map was constructed using water level elevation data collected on June 23, 2003 and is included as Figure IV-2. Water level elevations determined from the temporary off-site monitoring wells were used to estimate the shallow ground water flow pattern in the area immediately west of the southwest portion of the Site. This contour map exhibits an inferred ground water flow pattern similar to that depicted on Figure IV-1, with continued westward flow in the area west of the southwest portion of the Site.

2. Ground Water Analytical Results

The analytical results for the ground water samples are summarized in Tables IV-1A through IV-1D. Since applicable or relevant and appropriate requirements

(ARARs) have not been established, in accordance with USEPA RI/FS guidance, the data were compared with Screening Levels to confirm/refine the Potential Areas of Concern (PAOCs) identified based on review of historical Site data during completion of the PSE. For the purpose of this evaluation, the Illinois Tiered Approach to Corrective Action Objectives (TACO; 35 IAC 742) ground water remediation objectives were used as Screening Levels.[9] The Screening Levels are listed in Tables IV-1A through IV-1D. The Phase 2 laboratory data and data validation reports are submitted under separate cover. Ground water constituent concentrations that exceed the Screening Levels are summarized on Figure IV-3.

a. Metals

As shown on Figure IV-3, no total or dissolved metals concentrations exceeded the Screening Levels in monitoring wells G101, G103, G105, G106 and MW2, and only manganese exceeded the Screening Levels in wells G102 and MW5.[10] A low concentration of total thallium exceeding the Screening Level was detected in MW1; however, thallium was not detected in a duplicate sample collected concurrently from MW1. Concentrations of a broader list of metals exceeded Screening Levels in dissolved and/or total metals samples in wells located in the southwest portion of the Site and in the temporary monitoring wells located west of the southwest portion of the Site.

b. Sulfate

Sulfate concentrations exceeded the Screening Level of 400 mg/L in six of the monitoring wells: G107 (920 mg/L); MW1 (530 mg/L); MW3 (730 mg/L); MW6 (900 mg/L); MW7 (720 mg/L); and MW9 (1,700 mg/L).

[9] The Illinois TACO ground water remediation objectives for both Class I and Class II ground water (35 IAC 742; Appendix B, Table 1) are presented for screening purposes, with concentrations exceeding the more stringent standards (Class I) shown in bold type.

[10] It is noted that the manganese concentrations detected in upgradient wells G102 and MW5 likely represent natural background conditions in the ground water.

c. VOCs and SVOCs

No VOCs were detected in any of the ground water samples. With only one exception, no SVOCs were detected in any of the ground water samples. The SVOC caprolactam was detected in G107 at an estimated concentration of 0.00295 mg/L and in MW4 at a concentration of 0.1 mg/L. According to USEPA's Integrated Risk Information System (IRIS), caprolactam is used in the manufacture of synthetic fibers, especially nylon, and is therefore not believed to have been used on-site for the historical manufacture/processing of zinc/zinc compounds or for any other purpose. Caprolactam does not have an Illinois TACO ground water remediation objective. However, as the USEPA Region 9 Preliminary Remediation Goal (PRG) for this compound in "tap water" is 18 mg/L, its occurrence at the Site does not appear to pose an unacceptable risk; this compound therefore has not been designated as a PCOC for ground water.

d. PCBs

No PCBs were detected in any of the ground water samples.

3. Discussion

Based on the ground water sampling results for dissolved metals samples, zinc, cadmium, iron, lead, manganese and thallium are designated as PCOCs for ground water. The highest dissolved metals concentrations in ground water were detected in MW7. MW7 was installed at a location immediately downgradient (west) of a predicted area of concern (AOC) for soils. This potential source area is depicted on Figures IV-3 and VI-2 of the Phase 1 Technical Memorandum.

As shown on Figure IV-3, an area including the southwestern portion of the Site and a small off-Site area south and west of the western Site boundary (wooded area on an industrial property) is designated as a PAOC for ground water.[11]

[11] The non-toxic inorganic constituents iron, manganese and sulfate were not considered in the estimation of the ground water PAOC.

B. Surface Water Investigation

1. Surface Water Analytical Results

The analytical results for the surface water samples are summarized in Tables IV-2A through IV-2D. Again, since ARARs have not been established, in accordance with USEPA RI/FS guidance, the data were compared with Screening Levels to confirm/refine the PAOCs identified based on review of historical Site data during completion of the PSE. For the purpose of this evaluation, the Illinois Water Quality Standards: 35 IAC 302 Subpart B (General Water Quality Standards), and 35 IAC 302 Subpart D (Secondary Contact and Indigenous Aquatic Life Standards) were used as Screening Levels. The Screening Levels are listed in Tables IV-2A through IV-2D. The Phase 2 laboratory data and data validation reports are submitted under separate cover. Surface water constituent concentrations that exceed the Screening Levels are summarized on Figure IV-4.

a. Metals

With the exception of sample SW-ED-16, collected in the Eastern Drainageway near Lake Hillsboro, and samples SW-WD-11 and SW-WD-12 collected in the Western Drainageway, each surface water sample collected in both drainageways contained zinc concentrations that exceeded the Screening Level of 1 mg/L (ranged from 1.2 mg/L and 26 mg/L).[12] In addition, samples SW-WD-PS, SW-WD-PN, and SW-WD-9 contained cadmium concentrations that exceed the Screening Level of 0.05 mg/L (ranged from 0.069 mg/L to 0.23 mg/L). Finally, samples SW-WD-8 and SW-WD-10 contained iron concentrations that exceeded the Screening Level of 2 mg/L (3.2 mg/L and 15 mg/L, respectively).

[12] It is noted that the zinc concentration detected at SW-ED-11 (1.2 mg/L) likely represents background surface water conditions in the Eastern Drainageway. The Eastern Drainageway originates at or near this offsite location, which exclusively receives runoff from a sports playing field located north of the Site (i.e., no surface water drainage from the Site occurs to this portion of the Drainageway).

b. Sulfate

None of the sulfate concentrations detected in the surface water samples exceeded the Screening Level of 500 mg/L. Sulfate concentrations ranged from 21 mg/L to 450 mg/L, with the highest concentrations detected in the Western Drainageway.

c. VOCs and SVOCs

No SVOCs were detected in any of the surface water samples.No VOCs were detected at concentrations exceeding their respective screening levels. The VOC cis-1,2-dichloroethene was detected in surface water samples SW-WD-9 and SW-WD-PN at concentrations of 0.002 mg.L and 0.022 mg/L, respectively. The VOC trichloroethene (TCE) was also detected in these two surface water samples at concentrations of 0.0063 mg/L and 0.0014 mg/L, respectively.

d. PCBs

No PCBs were detected in any of the surface water samples.

2. Discussion

Based on these results, cadmium, iron and zinc were identified as PCOCs for surface water in the Western Drainageway. Only zinc was identified as a PCOC for surface water in the Eastern Drainageway. With the exception of a portion of the Eastern Drainageway proximal to Lake Hillsboro, portions of both drainageways immediately downstream of the Site are considered PAOCs for surface water.

C. Supplementary Residue Sampling

The analytical results for the residue pile samples are summarized in Table IV-3. With the exception of one composite sample collected from residue Pile RR2-11, each composite sample had a TCLP lead concentration in excess of the RCRA hazardous waste threshold of 5.0 mg/L.[13] The TCLP lead concentrations in Pile RR2-11 ranged

[13] 40 CFR 262.11.

from 2.2 mg/L to 18 mg/L. The TCLP lead concentrations in Pile RR1-3 ranged from 23 mg/L to 28 mg/L. The TCLP lead concentrations in Pile MP1-21 ranged from 18 mg/L to 230 mg/L.

Based on these results, TCLP lead continues to be considered a PCOC for the residues, and the piles designated RR1-3, RR2-11 and MP1-21 continue to be designated as PAOCs for residues.

D. pH Soil Sampling

The pH soil sampling results are summarized in Table IV-4. The soil pH values ranged from 4.3 to 7.9 Standard Units. These data will be used to assess pH dependent soil remedial objectives for the migration to ground water pathways in the Baseline Risk Assessment.

V. MODIFIED SITE CONCEPTUAL MODEL

Based on an evaluation of pre-existing site data presented in the PSE Report, affected environmental media, PCOCs, PAOCs, and potential exposure routes were identified as a preliminary Site Conceptual Model (SCM). Based on the Phase 2 sampling data for ground water and surface water, the SCM has been modified as follows:

POTENTIAL CONTAMINANTS OF CONCERN (PCOCs)					
On-Site Soil	**Sediment – Western Drainageway**	**Sediment – Eastern Drainageway**	**Residues**	**Ground Water**	**Surface Water**
Analytical Fractions					
TAL-Metals	**TAL-Metals**	**TAL-Metals**	**TCLP Metals**	**TAL-Metals**	**TAL-Metals**
Cadmium	Antimony	Antimony	TCLP-Lead	Cadmium	Cadmium
Lead	Arsenic	Arsenic		Lead	Chromium
Zinc	Beryllium	Beryllium		Manganese	Copper
	Cadmium	Cadmium		Thallium	Lead
	Lead	Lead		Zinc	Manganese
	Silver	Silver		Iron	Zinc
	Thallium	Thallium			Iron
	Zinc	Zinc			
	Organics	**Organics**		**Other Inorganics**	**Other Inorganics**
	Vinyl Chloride	Vinyl Chloride		Sulfate	Sulfate
					Organics
					Cis 1,2-Dichloroethene
					Trichloroethene

As compared with the PCOC summary included in the Phase 1 Technical Memorandum, cadmium was added as a PCOC for surface water. No specific modifications to the PCOC summary included in the RI/FS Work Plan were made for any other media.[14]

[14] Dissolved metals concentrations were used in determination of PCOCs for metals in ground water.

Based on exceedances of Screening Levels, the PAOCs for ground water and surface water are depicted on Figures IV-3 and IV-4, respectively, and are summarized as follows:

POTENTIAL AREAS OF CONCERN (PAOCs)				
On-site Soil	**Sediment**	**Residues**	**Ground Water**	**Surface Water**
Area 1; Area 2; Area 3; Area 4 Western Area	Western Drainageway; Eastern Drainageway	RR1 Stockpiles ; RR2 Stockpiles ; MP Stockpiles	SW Part of Site and Off-Site Area Immediately Adjacent	Western Drainageway; Eastern Drainageway

This summary table is identical to the PAOC summary provided in the Phase 1 Technical Memorandum, with the exception of the addition of a small off-Site area to the PAOC for ground water.

Based on a qualitative evaluation, the following potential on-Site and off-Site exposure routes have been identified:

POTENTIAL EXPOSURE ROUTES							
	On-Site Soil	**Residues**	**On-Site Sediments**	**Off-Site Sediments**	**On-Site Ground Water**	**Off-Site Ground Water**	**Surface Water**
Potentially Affected Population	Construction Worker; Employee; Tresspasser; Future Resident[15]; Ecological Receptors	Construction Worker; Employee; Trespasser; Ecological Receptors	Construction Worker; Employee; Trespasser; Future Resident[15]; Ecological Receptors	Resident; Ecological Receptors	Construction Worker; Employee; Future Resident[15]	Resident	Construction Worker; Employee; Trespasser; Future Resident; Ecological Receptors
Exposure Route(s)	Ingestion/ Inhalation; Soil Leaching to Ground Water; Potential Ecological Impacts	Ingestion/ Inhalation; Residue Leaching to Ground Water	Ingestion/ Inhalation; Soil Leaching to Ground Water	Ingestion/ Inhalation; Soil Leaching to Ground Water; Potential Ecological Impacts	Ingestion	Incidental Residential Exposure	Secondary Residential Exposure; Potential Ecological Impacts

No specific modifications were made to the Potential Exposure Routes summary presented in the Phase 1 Technical Memorandum based on the Phase 2 RI data. As

[15] This scenario is hypothetical, as residential development of the Site is not permitted under current zoning ordinances.

discussed in the RI/FS Work Plan, the Site Conceptual Model will be modified and supplemented as necessary during the course of the RI/FS, as the data are evaluated.

Notes:

Exceeds Most Stringent Illinois General Water Quality Standards
Detection Limit Above Screening Level
A = Analyte was detected in the method blank
B = Analyte was detected between the method detection limit and the reporting limit
C = Elevated detection limit due to matrix effect
J = Estimated Value
U = Indicates undetected at concentration listed
NS = Not sampled
R = Non Detected Results Rejected
-- No Criterion

[1] Value is based on the more stringent of the human health-based priority or non-priority toxic pollutants. Criteria only listed for constituents without Illinois Surface Water Standards that were detected at least once in surface water.
